# Network analysis project

City street analysis from a network and topology perspective

Riku Laine

25 helmikuu, 2019

### Introduction

The purpose of this document is to illustrate the statistical model fitting procedure used to infer street network properties that affect travel times in cities.

### The data

- Street network metrics from 197 cities. 36 different variables.
- Cities from Inrix scorecard listing.
- It was observed that some of the areas obtained were close to zero square kilometers or clearly too small to be correctly mapped (see Table 1). It was decided that if the logarithm of the graph area is bigger than the mean of the logarithms of the areas subtracted by one standard deviation of the log areas, the city would be included in the analysis. I.e. include the city if log(graph\_area) > mean(log(graph\_area)) sd(log(graph\_area)). Subsequently 17 cities were removed.

Table 1: 20 smallest graph areas (in m<sup>2</sup>).

city_name	graph_area
gold coast	6425
halifax, ns	336663
copenhagen	1563934
johannesburg	2475008
riyadh	2623295

city_name	graph_area
perth	5737402
quito	5795797
brisbane	8673674
edinburgh	9323960
durban	12132292
adelaide	14744114
geneva	18968697
brussels	27433896
la paz	38598092
bilbao	41308764
glasgow	46921762
lille	49505449
melbourne	51593188
southampton	56571368
leicester	59221795

```
# Remove observations according to prespecified rule
log_area <- log(metrics$graph_area)

cutpoint <- mean(log_area) - sd(log_area)

cat("Cutpoint in sq. kms:", exp(cutpoint)/1e6)

## Cutpoint in sq. kms: 49.80604

metrics <- subset(metrics, log_area > cutpoint)

row.names(metrics) <- NULL # Reset rownames</pre>
```

## Analysis

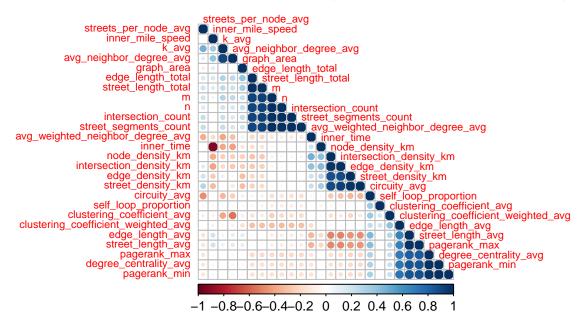

The goal is to build a statistical model to explain the variable inner\_mile: "The time it takes to travel one mile into the central business district during peak hours" (Inrix).

#### Correlations

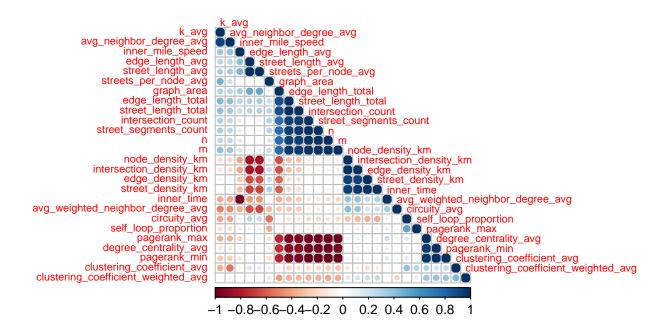

It as expected that the variables show extreme values of correlation. Below are figures for Pearson and Spearman rank correlation. Latter indicates correlations with the variable ranks, order of greatness, and doesnt expect linear dependence. Illuminating example given in the relationship with the maximum PageRank value pagerank\_max and number of nodes n.

```
title(sub = "Spearman rank correlation")
par(mfrow=c(1,2))
plot(metrics$n, metrics$pagerank_max, main = "Linear scale")
plot(metrics$n, metrics$pagerank_max, log = 'xy', main = "Log-log scale")
par(mfrow=c(1,1))
```

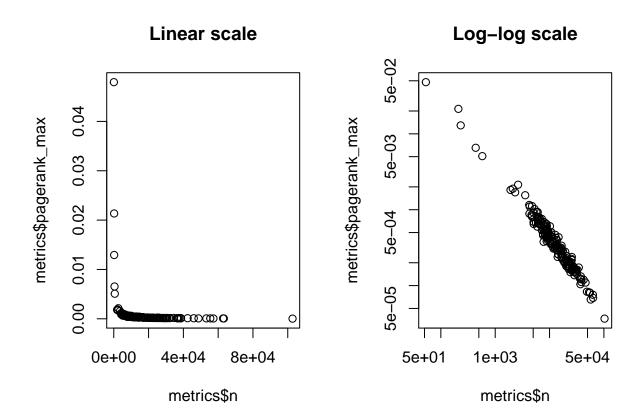

## Correlation plots, ordering by hierarchical clustering

#### Pearson correlation

Spearman rank correlation

## Modelling

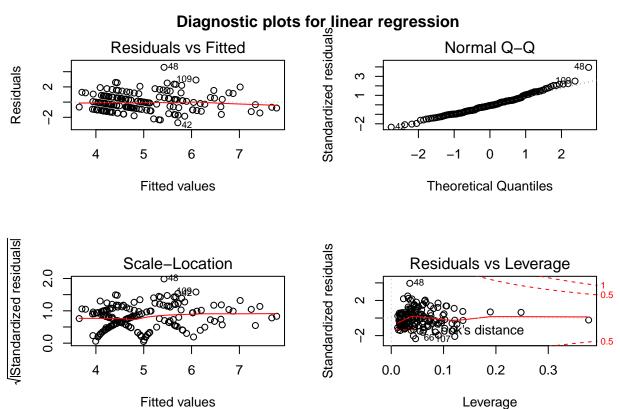

It is hypothesized that the dependence between the properties and traffic time is linear.

#### Variable selection

Basis for variable selection is reported at this document. Some of the variable selection and construction was based on the assumption that if a street was a two-way street the library broke it down as two one-directional edges between nodes, i.e. initersections.

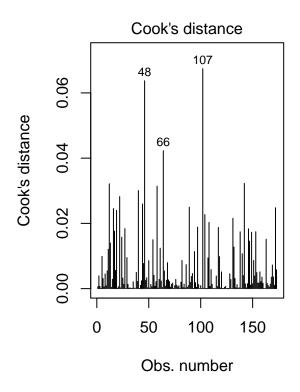

During the model fitting seven misspecified networks were identified by Cook's distance from Acapulco, Waterloo (Ontario), Villahermosa, Mecca, Leicester, Belfast and Medellin. For all of them but Waterloo, Ontario, the misspecification was the result of OpenStreetMap service lacking their respective border polygon. Usually the service had the location of the cities as a point, but lacked the polygon, and then the next polygon in list (obtainable via search from here) was usually in the US. Waterloo, Ontario was excluded from analysis as it was evident that the Inrix analysis also included the street network of the neighbouring city of Kitchener.

ncvTest(met_linear)
```

## Non-constant Variance Score Test
## Variance formula: ~ fitted.values
## Chisquare = 5.908333, Df = 1, p = 0.015069

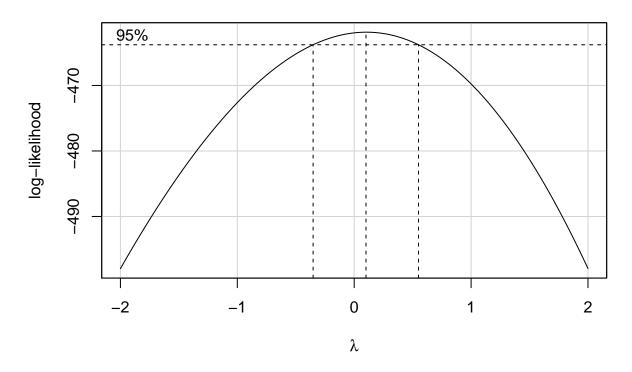

QQ-plot indicates that that there are some deviations from the assumptions. ncvTest confirms that variance is not constant. From the Cook's distance figure it is evident that no significant outliers are anymore present.

Observations 48, 66 and 107 (Dublin, Helsinki and Naberezhnye Chelny) have been validated to be correct.

Let's conduct Box-Cox to obtain best power transformation for our response:

boxCox(met\_linear)
title("Box-Cox method for power transformation")

## Box-Cox method for power transformation

#### summary(powerTransform(met\_linear))

```

## Likelihood ratio test that transformation parameter is equal to 0
   (log transformation)
##
                               LRT df
                                        pval
##
## LR test, lambda = (0) 0.2069113 1 0.6492
## Likelihood ratio test that no transformation is needed
                             LRT df
## LR test, lambda = (1) 15.7905 1 7.0757e-05
```

From the function summary it is seen that transformation is needed and that it should be log transformation. Let's redefine model with response transformed to log scale.

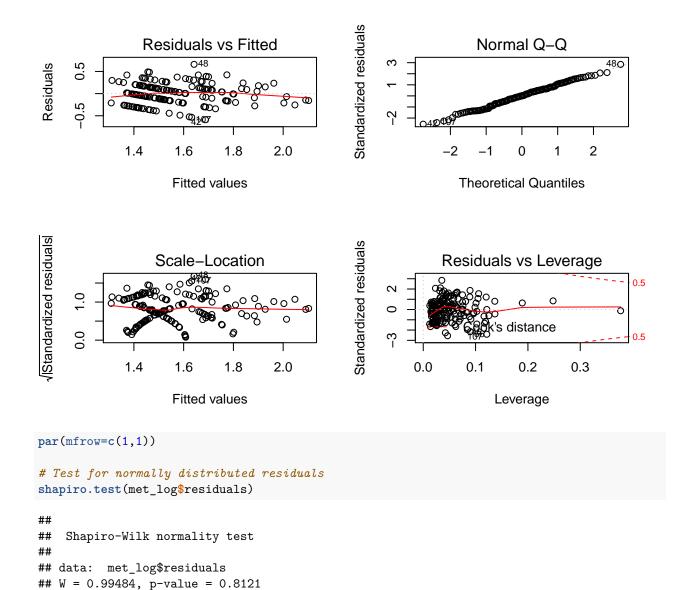

Notable is that now interpreting as in wiley etc etc.

```
# Fit linear model with response in log scale.
met_log <- lm(log(inner_time) ~ ., data = metrics[outliers_to_omit, regression_vars])

# Print model summaries

## Heteroscedasticity 0.10783 0.7426 Assumptions acceptable.
```

The unconstant variance has now been corrected as proposed by Weisberg. The tails of the QQ-plot do not deviate anymore and the residuals are normally distributed. Also Tukey's tests for nonadditivity returned non-significant.

Therefore it can be concluded that the model fits.

#### Results

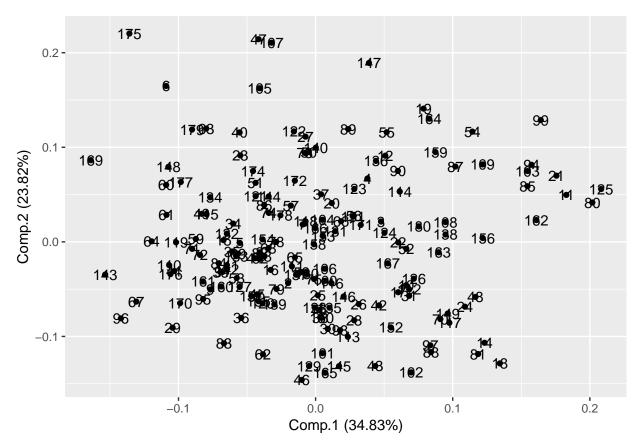

Table 2: Coefficients as percentage change and their p-values

Perc. change	P-value	Significant?
-6.25	0.253	No
0.0158	0.845	No
0.754	0.031	Yes
-0.00196	0.35	No
382	0.77	No
48400	0.928	No
-88	0.157	No
-44.2	0.002	Yes
	-6.25 0.0158 0.754 -0.00196 382 48400 -88	-6.25     0.253       0.0158     0.845       0.754     0.031       -0.00196     0.35       382     0.77       48400     0.928       -88     0.157

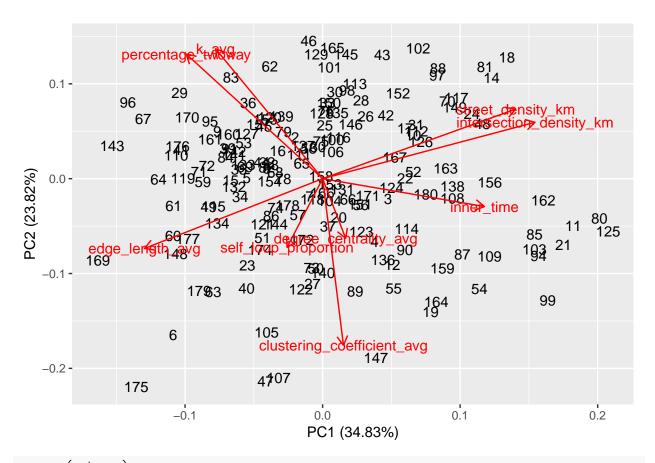

From the above table it is seen that for each unit change in e.g intersection density, the average inner\_time increases by 0.75%. Also for each percentage twoway roads added, the average "time it takes to travel one mile into the central business district during peak hours" is reduced by 44.2%.
